## Glossary

---

- **Graph  $G$  ( $V$ ,  $E$ ):**
  - **$V$ :** vertices set
  - **$E$ :** edges set
- **Degree:** number of vertices
- **Walk:** series of connected vertices
- **Path:** walk without repeated vertices
- **Closed walk:** walk where  $v_0 = v_n$
- **Cycle:** closed walk without repeating vertices
- **Euler path:** visit each edge exactly once
- **Hamilton path:** visit each vertex exactly once
- **Directed graph:** edges are ordered pairs
- **Ancestor:**  $v$ , **Successor:**  $u$  in

- **$\deg_{in}(v)$ :** number of incoming edges into  $v$

- $\text{deg}_{\text{out}}(v)$ : number of outgoing edges into  $v$

## Graph Representation

---

### Adjacency matrix:

matrix where  $A_{uv} = \begin{cases} 1 & \text{if } (u, v) \in E \\ 0 & \text{otherwise} \end{cases}$

**Graph:**

**Matrix:**

$$\begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix}$$

### Adjacency list

Array of linked lists, where  $\text{Adj}[u]$  contains a list containing all the neighbors of  $u$ .

**Graph:** Same as above

**List:**

## Runtimes

	Matrix	List
Find all neighbors of $v$	$\mathcal{O}(n)$	$\mathcal{O}(\deg_{out}(v))$
Find $v \in V$ without neighbors	$\mathcal{O}(n^2)$	$\mathcal{O}(n)$
Check if $(v, u) \in E$	$\mathcal{O}(1)$	$\mathcal{O}(1 + \min(\deg_{out}(v), \deg_{out}(u)))$
Insert edge	$\mathcal{O}(1)$	$\mathcal{O}(1)$
Remove edge $v$	$\mathcal{O}(1)$	$\mathcal{O}(\deg_{out}(v))$
Check whether an Eulerian path exists or not	$\mathcal{O}( V  *  E )$	$\mathcal{O}( V  +  E )$

## Algorithms

### Depth-First Search (DFS)

Used mainly to check whether a Graph can be topological sorted or not ( $\Leftrightarrow$  has a cycle). A **topological sorting** of a graph it's a sequence of all its nodes with the property that a node  $u$  comes after a node  $v$  **if and only if** either a walk from  $v$  to  $u$  exists or  $u$  cannot be reached starting from  $v$ .

## Pseudocode

```
1 DFS(G):  
2   for (v in V not marked):  
3     DFS-Visit(v)
```

```
1 DFS-Visit(v):  
2   t = 0  
3   pre[v] = t++  
4   marked[v] = true  
5   for ((u, v) in E not marked)  
6     DFS_Visit(u)  
7   post[u] = t++
```

## Runtime

Operations	$T(n) \in \Theta( E  +  V )$
Memory	$T(n) \in \Theta( V )$

## Edge classification (post and pre numbers)

**Example:** DFS(A) got called

This graph generate the following tree (rotated of 90 degree to save space):

Pre and post number	Name of the edge $(v, u) \in E$
$pre(u) < pre(v)$ and $post(u) < post(v)$	Not possible
$pre(u) < pre(v)$ and $post(u) > post(v)$	<b>forward</b> or simply no name, since it is part of the tree
$pre(u) < pre(v)$ and $post(u) < post(v)$ but $(u, v) \notin E$	<b>forward edge</b>
$pre(u) > pre(v)$ and $post(u) > post(v)$	<b>back edge</b>
$pre(u) > pre(v)$ and $post(u) < post(v)$	<b>cross edge</b>
$pre(u) < pre(v)$ and $post(u) < post(v)$	Not possible

**Remark:**  $\nexists$  back edge  $\Leftrightarrow \nexists$  closed walk (cycle)

## Breadth-First Search (BFS)

Instead of searching through the depth of a graph, one can also go first through all the successor of the root with the BFS algorithm.

### Pseudocode

```

1  BFS(G):
2    for (v in V not marked):
3      DFS-Visit(v)

```

```

1 DFS-VISIT(v):
2     Q = new Queue()
3     active[v] = true //used to check whether a vertex is in the queue or not
4     enqueue(v, Q)
5     while (!isEmpty(Q)):
6         w = dequeue(Q)
7         visited[w] = true
8         for ((w, x) in E):
9             if(!active[x] && !visited[x]):
10                 active[x] = true
11                 enqueue(x, Q)

```

## Runtime

Operations	$T(n) \in \Theta( E  +  V )$
Memory	$T(n) \in \Theta( V )$

## Find shortest path in DAG (Directed Acyclic Graph)

We can compute a recurrence following the topological sorting of the graph.

## Pseudocode

```

1 ShortestPath(V):
2     d[s] = 0, d[v] = inf
3     for (v in V \ {s}, following topological sorting):
4         for (u, v, s.t. (u, v) in E):
5             d[v] = min(d[u] + c(u,v))

```

## Runtime

$T(n) \in \mathcal{O}(|E| * |V|)$  if adjacency list is given

## Dijkstra

Used to find the shortest (cheapest) path between two nodes in a graph.

**Remark:** The graph must **not** have negative weights

## Pseudocode

```

1 DIJKSTRA(G, s):
2     for (v in V):
3         distance[v] = inf
4         parent[v] = null
5     distance[s] = 0
6     Q = new Queue()
7     insert(s, 0, Q) // insert s into the queue Q, with priority 0 (min)
8     while(!isEmpty(Q)):
9         u = Q.extractMin() // extract from Q the node with minimum distance
10        for ((u, v) in E):
11            if (parent[v] == null):
12                distance[v] = distance[u] + w(u, v)
13                parent[v] = u
14            else if (distance[u] + w(u, v) < distance[v]):

```

```
15     distance[v] = distance[u] + w(u, v)
16     parent[v] = u
17     decreaseKey(v, distance[v], Q)
```

## Runtime

$T(n) \in \mathcal{O}(|E| * |V| * \log(|V|))$  if implemented with a Heap.

If implemented with a **Fibonacci-Heap**:  $T(n) \in \mathcal{O}(|E| + |V| * \log(|V|))$

## Bellman-Ford
